Abstract — This paper proposes a new three-phase telecom rectifier system in which sinusoidal input current at unity power factor is achieved. Inherent natural wave-shaping capability of the polyphase transformer together with an active current wave-shaping technique result in a significant reduction of input and output filter requirements associated with switching ripple and EMI. Further, the proposed scheme is shown to have higher efficiency because it does not employ an intermediate dc-dc conversion stage and has a relatively small number of switches and diodes. The proposed scheme has a regulated and isolated output voltage at low level so that the scheme is suitable for telecom rectifier. The operation principle is described along with a design example and a comparative evaluation. Experimental results on a 1.5kW prototype are provided to validate the proposed concept.

Keywords- telecom rectifier, waveshaping, three-phase power factor correction, polyphase transformer

I. INTRODUCTION

In last decades telecommunication and data communication equipments have increasingly been used. It is required that a front end diode rectifier be highly efficient and have high power density and low cost.

Due to inherent nonlinear switching diode rectifiers suffer from large contents of input current harmonics resulting in many serious problems in power system. There have been many approaches to eliminate the harmonics in the telecommunication rectifier system.

A six-switch PWM rectifier demonstrates high input power factor, but requires complicated measurements and feedback control and is in general costly [1]. A single-switch three-phase PFC is simple in control and low in cost, but suffers from high switch current rating and high EMI due to discontinuous mode operation [2] and therefore can not be applied to higher power than 10KW.

A three-phase rectifier employing three single-phase boost PFC circuits with direct coupling operates in the continuous conduction mode (CCM) and therefore allows high power factor and small EMI filters [3]. However, the output voltage is high due to boost operation and requires the use of a following DC-DC converter stage to get a low voltage such as 48VDC in the telecommunication system.

Recently, an 18-pulse isolated rectifier has been proposed to provide a regulated dc voltage at low level for telecommunication equipments [4]. This scheme is attractive in that natural power factor correction is achieved by a polyphase autotransformer, and control is simple since current balancing can be obtained by connection of secondary windings of high frequency transformers. However, the scheme has a relatively large number of components and may not meet the IEEE519 current distortion limits for a case of having low short circuit current to demand load current ratio.

In this paper, a three-phase telecom rectifier based on arrangement of a polyphase autotransformer and an active wave-shaping technique is proposed as shown in Fig. 1. The proposed approach incorporates a 12-pulse autotransformer

![Fig. 1 Proposed telecom rectifier system](image-url)
and two three-phase diode rectifiers, each followed by a full bridge converter operating at continuous conduction mode. An active wave shaping technique is applied to the proposed scheme resulting in sinusoidal input currents at unity power factor. The advantages of the proposed scheme are:

- Sinusoidal input current at unity power factor meeting with IEEE519 current distortion limits.
- Higher efficiency due to no use of an intermediate dc-dc conversion stage and use of relatively small number of components.
- Significantly reduced input and output filter requirement associated with switching ripple and EMI due to the proposed active wave-shaping technique based on the polyphase transformer arrangement.
- Isolated and regulated dc voltage at low level applicable to telecom equipments.
- Suitable for higher power application due to CCM operation in the whole range of load variation.

The operation principle is described along with the reference signal generation and control method in the following section.

II. PROPOSED ACTIVE DIODE RECTIFIER SYSTEM

A. Operating Principles

Fig. 1 shows the basic configuration of the proposed rectifier system that employs a three-phase autotransformer and two three-phase diode rectifiers, each followed by a current source full bridge converter. The three-phase autotransformer is employed to supply two sets of three-phase voltages for each diode bridge which lead and lag the input source voltage by 15°, respectively.

The KVA rating of the autotransformer is 0.24P_o, and this considerably reduces the size and weight compared to the equivalent ∆-Y transformer which has a KVA rating of 1.035 P_o [5]. The operating principle is illustrated with various waveforms shown in Fig. 2.

The rectifier input currents can be expressed in terms of rectifier output currents, which are inductor currents, and switching functions of the diode bridge as,

\[
\begin{align*}
\begin{bmatrix}
    i_{a1} \\
    i_{b1} \\
    i_{c1}
\end{bmatrix} &= \begin{bmatrix}
    S_{a1} \\
    S_{b1} \\
    S_{c1}
\end{bmatrix} \cdot i_{L1}, \\
\begin{bmatrix}
    i_{a2} \\
    i_{b2} \\
    i_{c2}
\end{bmatrix} &= \begin{bmatrix}
    S_{a2} \\
    S_{b2} \\
    S_{c2}
\end{bmatrix} \cdot i_{L2}
\end{align*}
\]

From the autotransformer connection, the input current can be expressed in terms of rectifier input currents as [5],

\[
i_a = i_{a1} + i_{a2} + 0.1547 \cdot (i_{c2} - i_{b2} + i_{b1} - i_{c1})
\]

Then, the phase ‘a’ input current can be expressed in terms of the inductor currents and the switching functions as,
\[ i_a = \left\{ S_{a1} + 0.1547 \cdot (S_{b1} - S_{c1}) \right\} \cdot i_{L1} + \left\{ S_{a2} + 0.1547 \cdot (S_{c2} - S_{b2}) \right\} \cdot i_{L2} \] (3)

It can be noted from equation (3) that the input current is determined by the inductor current. If the inductor current is dc, the input current would have 12-pulse characteristics due to natural wave-shaping capability of the autotransformer. Now, the inductor current is controlled to have a wave shape given in the following,

\[ i_{L1}^*(t) = \frac{K}{2\sqrt{2}V_{LL}} \cdot \text{Min}\left\{\left|v_{ab}(t)\right|,\left|v_{be}(t)\right|,\left|v_{ca}(t)\right|\right\} \] (4)

\[ i_{L2}^*(t) = i_{L1}^*(t - \frac{30^\circ}{\omega}) \] (5)

Here, \( K = \frac{I_{L,P,k}}{I_o} \) is a scale factor which can be determined by ratio between input line-to-line voltage \( V_{LL} \) and output dc voltage \( V_o \). The desired wave shape of the inductor current is portion of the line-to-line voltages, shown as a thick line in Fig. 2. Each current source full bridge converter is operated in CCM to shape its input inductor current as given in equations (4) and (5). Modulating the inductor current as such results in sinusoidal input currents at unity power factor as shown in Fig. 2.

In the mean time the primary current of the high frequency transformer is determined by the switching function of the full bridge converter as,

\[ i_{p1}(t) = S_1(t) \cdot i_{L1}(t) \]
\[ i_{p2}(t) = S_2(t) \cdot i_{L2}(t) \] (6)

Then the capacitor input current can be expressed as,

\[ i_d(t) = i_{d1}(t) + i_{d2}(t) \]
\[ = \frac{N_p}{N_s} \cdot \left\{ i_{p1}(t) + i_{p2}(t) \right\} \] (7)

As we can see from Fig. 2 the large low order (6th) harmonic in the two diode currents add up and does not appear in current \( i_d \), and therefore filter output capacitance is greatly reduced.

The method of generating reference signals for inductor currents is shown in Fig. 3. The normalized wave shape references, \( i_{L1,N} \) and \( i_{L2,N} \) are stored in look-up table and is synchronized with a line-to-line voltage by means of zero-cross detecting and phase locked loop circuits. The magnitude references for inductor currents are also obtained by a signal from output voltage regulation.

The input and output relationship on average values of the propose rectifier system gives,

where operating range of the duty ratio is 0.5＜D＜1.

The average rectifier output voltage \( V_{d,av} \) becomes [5].

\[
V_{d,av} = 1.035 \times 1.35 \times V_{LL}
\]  
(9)

From equation (8) and (9) the turn ratio of the high frequency transformer can be determined by,

\[
N = \frac{N_P}{N_S} > 1.397 \cdot \frac{V_{LL}}{V_o}
\]  
(10)

Also, the average value of the inductor current becomes,

\[
I_{L,av} = 0.55 \cdot I_{L,pk}
\]  
(11)

From equations (8) and (11), the scale factor \( K \) can be obtained by,

\[
K = 0.65 \cdot \frac{V_o}{V_{LL}}
\]  
(12)

B. Design Example

As a design example for the proposed diode rectifier system the following parameters are assumed:

\[
P_o = 12kW; V_{LL} = 220V; V_o = 48V
\]

The output current \( I_o \) is given by,

\[
I_o = \frac{P_o}{V_o} = 250A
\]  
(13)

Then, by letting the nominal duty ratio be \( D = 0.6 \) the turns ratio can be calculated by equations (8) - (10),

\[
N_P : N_S = 8 : 1
\]  
(14)

Table I summarizes the expression for voltage and current ratings of the transformers and switching devices. The current ratings of the component in the proposed scheme depend on the duty ratio of the switch. The design values for a 12kW rectifier system shown as a design example are listed corresponding to the expressions.

C. Comparative Evaluation of the Proposed Rectifier

In this section a comparative evaluation of the proposed scheme and several other schemes concerning efficiencies, component counts, and realization efforts etc. is given. The schemes considered for evaluation include single-switch PFCs, six-switch PWM rectifiers, three single-phase PFCs[3], and 18-pulse rectifiers[4].

The assumed operating conditions for evaluation are listed below.

- The utility source is ideal with a zero internal impedance.
- The components are ideal, unless specified otherwise.
- The system parameters given in equations (13)-(15) are used in the calculation of switch utilization and losses.
- The switching frequency is constant with $f_{sw} = 30$ kHz.
- The maximum peak-to-peak ripple of the inductor current is 10% of its rms value.
- The intermediate dc voltages are 400V for single-switch PFCs, six-switch PWM rectifiers and three single-phase PFCs[3], 260V for 18-pulse rectifiers, and 307V for the proposed scheme, respectively.

The calculation of switch utilization, and normalized switching and conduction losses is based on the equations obtained in the literature [7]. The evaluation result is listed in Table II.

The proposed scheme employs a low kVA(0.24$P_0$) polyphase autotransformer followed by diode bridges as a front-end, resulting in natural waveshaping characteristic similar to the 18-pulse rectifier. Since it does not use switches operating at high frequency in the front-end conversion stage, the use of input filter is not necessary and requirement of using EMI filter is reduced. Due to continuous conduction operation in the dc-dc converter the required EMI filter size is further reduced. The 18-pulse rectifier, which has also significantly reduced EMI filter size, may need to use a small input filter to meet the IEEE 519 harmonic standard.

The proposed scheme shows a low switch utilization in the dc-dc conversion stage. The total number of switches and diodes of the proposed scheme is fairly low, and especially the number of fast recovery diodes is lowest, resulting in lower power losses and cost.

The switching loss of the proposed scheme is approximately half of that of the 18-pulse rectifier while the conduction loss of the proposed scheme is approximately double of that of the 18-pulse rectifier. This is because the dc-dc converter employed in the proposed scheme is a current-fed type with the duty cycle ranging between 0.5 and 1 while that of the 18-pulse rectifier is a voltage type with the duty cycle ranging between 0 and 0.5.

Among the five schemes compared, the proposed scheme is shown to have the highest efficiency due to the following reasons: (1) The total power switch losses of the proposed scheme is shown to be the smallest, (2) an intermediate dc-dc conversion stage is not employed in the proposed scheme, (3) the total number of switches and diodes is relatively low.

### III. EXPERIMENTAL RESULTS

A laboratory prototype has been built and the experimental results are provided. The experimental waveforms for the proposed scheme are shown in Fig.4. The system parameters for the experiment are as follows:

- $P_0: 1.5$ kW
- Supply : 220V(line-to-line, RMS), 60Hz
- $V_0: 48$ VDC
- Dc link capacitor $C_o=3300uF$, Inductor $L_1, L_2=5mH$.

Fig. 4(a) shows the inductor current $i_{L1}$ whose waveform is
shaped by the full bridge converter. The rectifier input current $i_{a1}$, shown in Fig. 4(b), has 120° of discontinuous period. This results in near sinusoidal input current, as shown coincident in Fig. 4(c). The measured THD of the input current is 2.7%.

Based on these results, the experimental results agree with the analysis shown in Fig. 2 very well. The validity of the control method is verified.

IV. CONCLUSIONS

In this paper a new telecom rectifier system is proposed to draw sinusoidal input current at unity power factor so that the proposed scheme meets with IEEE519 current distortion limits for load with any short circuit current to load current ratio.

Based on natural wave-shaping capability of the autotransformer with low kVA rating(0.24Po) the proposed active wave shaping technique significantly reduces input and output filter requirement associated with switching ripple and EMI.

The proposed scheme is also shown to have higher efficiency because it does not employ an intermediate dc-dc conversion stage and has a relatively small number of components. The proposed scheme has a regulated and isolated output voltage at low level and therefore is suitable for telecom rectifier. Experimental results on a 1.5kW prototype have been provided to validate the proposed concept.
